MULTIPARTITIONS, GENERALIZED DURFEE SQUARES AND AFFINE LIE ALGEBRA CHARACTERS

PETER BOUWKNEGT

Dedicated to Rodney J. Baxter on his 60th birthday

(Received 26 April 2000)

Communicated by I. Aitchison

Abstract

We give some higher dimensional analogues of the Durfee square formula and point out their relation to dissections of multipartitions. We apply the results to write certain affine Lie algebra characters in terms of Universal Chiral Partition Functions.

2000 Mathematics subject classification: primary 05A17, 05A19, 17B67, 81T40.

1. Introduction and background

In this paper we will consider certain generalizations of an identity, due to Euler, known as the Durfee square identity (see [3] for an excellent introduction and historical account)

\[(1.1) \quad \frac{1}{(q)_{\infty}} = \sum_{m \geq 0} \frac{q^{m^2}}{(q)_m (q)_m}, \]

where

\[(1.2) \quad (z; q)_M = \prod_{k=1}^{M} (1 - zq^{k-1}), \quad (q)_M \equiv (q; q)_M. \]

There are various ways to prove this identity. For instance, it follows as a limiting case of the \(q\)-analogue of Gauss’ formula for the basic hypergeometric series \(2\phi_1\) (see,
for example, [2]). The most lucid proof, however, employs the connection of (1.1) to partitions [10] (see also [8, 2]). Henceforth we identify partitions $\lambda = (\lambda_1, \lambda_2, \ldots)$, $\lambda_1 \geq \lambda_2 \geq \cdots \geq 1$, and their graphical presentation in terms of Young diagrams [2] (see, for example, Figure 1.1 for the partition $\lambda = (6, 4, 4, 2)$).

Now, recall that

$$z \frac{q}{z \frac{q}{M}} M_{n \times 0} = \sum_{m,n \geq 0} p_M(m,n) z^m q^n,$$

where $p_M(m,n)$ denotes the number of partitions of $n$ into $m$ parts in which no part exceeds $M$. In terms of Young diagrams, $p_M(m,n)$ is the number of diagrams with $n$ boxes such that there are $m$ rows and no more than $M$ columns.

Thus, the left-hand side of (1.1) is clearly the generating function for all partitions, while each summand on the right-hand side correspond to all partitions which fit at most an $m \times m$ ‘Durfee square’ in the upper left-hand corner of the Young diagram. (The $3 \times 3$ Durfee square for the partition $\lambda = (6, 4, 4, 2)$ is indicated in Figure 1.1.) Summing over all $m$ clearly generates the total set of partitions as well. This proves (1.1). In fact, by keeping track of the number of columns and rows in the above argument we have the following generalization of (1.1) due to Cauchy

$$\frac{1}{(zq)_m} = \sum_{m,n \geq 0} q^n z^m \left[ \begin{array}{c} M \\ m \end{array} \right],$$

where

$$\left[ \begin{array}{c} m \\ n \end{array} \right] = \frac{(q)_m}{(q)_n (q)_{m-n}},$$

for $0 \leq n \leq m$ (and zero otherwise), denotes the $q$-binomial (Gaussian polynomial).

Instead of dissecting partitions according to their maximal Durfee square, Andrews considered dissections by (maximal) rectangles whose base to height ratio is $r : s$ and obtained the following generalization of (1.4) [1]

$$\frac{1}{(zq)_M} = \sum_{i,j} \sum_{m \geq 0} q^{(r m + i) (s m + j)} z^{r m + i} \left[ \begin{array}{c} M + r m + i \delta_{j,s} - s m - j \\ r m + i \delta_{j,s} \end{array} \right].$$
where the sum over \((i, j)\) is over all pairs

\[
(i, j) \in \{(i, j) = (0, 0) \text{ or } 1 \leq i \leq r, \ 1 \leq j \leq s, \ (i, j) \neq (r, s)\}.
\]

In fact, the identity (1.6) is valid even if \(r\) and \(s\) are not relatively prime, as is obvious from Andrews’ proof. For \((r, s) = (1, 1)\), (1.6) reduces to (1.4), while for \((r, s) = (2, 1)\) it gives an identity which appears explicitly in Ramanujan’s lost notebook (see [3]). The proof of (1.6) was also sketched by Berkovich and McCoy in [6], and the \(M \to \infty\) limit of (1.6) was discussed by van Elburg and Schoutens in [7].

In this paper we will consider further generalizations of (1.6) by considering simultaneous dissections of multipartitions. The resulting formulas are useful in deriving expressions for the chiral characters of 2D conformal field theories (in particular the characters of modules of affine Lie algebras) in terms of so-called universal chiral partition functions (UCPF’s).

### 2. Durfee systems

We will be concerned with identities of the form

\[
\frac{1}{\prod_i (z_i q)_{M_i}} = \sum_k \sum_{n = K \cdot m + Q^{(k)}} \left( \prod_i z_i^{m_i + a^{(k)}_{ij}} \right) q^{(m_i + a^{(k)}_{ij}) (n + b^{(k)})} \frac{1}{\prod_i (z_i q)_{n_i}} \times \prod_i \left[ M_i + m_i - (n_i + b^{(k)}) \right]^{m_i},
\]

where \(K \in GL(n, \mathbb{Q})\) is a symmetric matrix and the sum over \(k\) is over a (finite) set of sectors. In each sector \(k\), the sum over \(m\) is over those \(m \in (\mathbb{Z}_+)^n\) (here \(\mathbb{Z}_+\) denotes the set of non-negative integers) such that \(K \cdot m + Q^{(k)} \in (\mathbb{Z}_+)^n\), while \(n = K \cdot m + Q^{(k)}\).

**Definition 2.1.** A Durfee system for \(K \in GL(n, \mathbb{Q})\), of length \(L\), is a collection of \(n\)-dimensional vectors, \((Q^{(k)}, a^{(k)}, b^{(k)}), k = 0, \ldots, L - 1\), such that (2.1) is satisfied for all \(M_i \in \mathbb{Z}_+\) and \(z_i (i = 1, \ldots, n)\).

Andrews’ \((r, s)\)-generalization of the classical Durfee formula, discussed in Section 1, can now be formulated as

**Theorem 2.2.** Let \(r, s \in \mathbb{N}\). A Durfee system of length \(L = rs\), for the \(1 \times 1\) matrix \(K = s/r\), is given by

\[
Q^{(i, j)} = j - 1 + \delta_{i,0} + \delta_{i,r} - \frac{s}{r} i \delta_{j,s},
\]

\[
a^{(i, j)} = i (1 - \delta_{j,s}), \quad b^{(i, j)} = 1 - \delta_{i,0} - \delta_{i,r},
\]

where \(k = (i, j)\) runs over the \(rs\) sectors as in (1.7).
In the remainder of this paper we restrict ourselves to non-negative integer-valued, symmetric matrices $K$, that is, $K \in GL(n, \mathbb{Z}_+)$, and Durfee systems $(Q^{(k)}, a^{(k)}, b^{(k)})$ of $n$-vectors with entries in $\mathbb{Z}_+$. In this case the sum in (2.1) is over all $m_j \geq 0$ and $n_j \in \mathbb{Z}_+$, and determined by $n = K \cdot m + Q^{(k)}$.

Before giving examples, let us first explore some consequences of (2.1). By replacing $z_i \rightarrow z_i q^{p_i}$ in (2.1), for some $p \in \mathbb{Z}^n$, using the expansion (Note that (2.3) itself can be interpreted as a length-1 Durfee system for the trivial matrix $K = 0$ with $(Q, a, b) = (0, 0, 1)$.)

\[
\frac{1}{(zq)_M} = \sum_{m \geq 0} (zq)^m \left[ \frac{M + m - 1}{m} \right],
\]

and shifting the summation variables, we find

\[
\prod_i \left[ \frac{M_i + N_i}{M_i} \right] = \sum_k \sum_{m \geq 0} q^{(m+a^{(k)}_i)(a^{(k)}_j)_{n_i}} \prod_i \left[ \frac{M_i + m_i - (n_i + b^{(k)}_i)}{m_i} \right] \times \left[ \frac{N_i + n_i - (m_i + a^{(k)}_i)}{n_i} \right].
\]

for arbitrary $p \in \mathbb{Z}^n$. Note that in this formula the summation variables $(m, n)$ appear on a more symmetrical footing.

By taking the limit $M_i \rightarrow \infty$ in (2.1) we find

\[
\frac{1}{(zq)_\infty} = \sum_k \sum_{m \geq 0} z^m \left( \prod_i \frac{m_i + a^{(k)}_i}{m_i} \right) \frac{q^{(m+a^{(k)}_i)(a^{(k)}_j)_{n_i}}}{\prod_i (q)_{m_i} (zq)_{n_i}},
\]

while by specializing (2.5) to $z_i = q^{p_i}$, we find a generalization of the classical Durfee formula (1.1)

\[
\frac{1}{(q)_\infty} = \sum_k \sum_{m \geq 0} q^{(m+a^{(k)}_i)(a^{(k)}_j)_{n_i}} \frac{1}{\prod_i (q)_{m_i} (q)_{n_i}},
\]

for any constant vector $p \in \mathbb{Z}^n$. Of course, this equation can also be obtained from (2.4) by letting all $M_i \rightarrow \infty$. Other interesting formulas are obtained by taking different specializations of (2.4).

The search for identities of the type (2.1) in dimension $n$ is greatly facilitated by using results in lower dimensions. Indeed, by putting $z_i = 0$ for some $i = i_0$ in (2.1), the right-hand side only receives contributions from the sectors $k$ for which $a^{(k)}_{i_0} = 0$. For those sectors only the term $m_{i_0} = 0$ contributes in the summation, and
(2.1) reduces to a similar identity in dimension $n - 1$. Summarizing, if we know identities for a $(n - 1) \times (n - 1)$ sub-block of $K$, then we learn about the components $(Q_i^{(k)}, a_i^{(k)}, b_i^{(k)})$, $i \neq i_0$, for all sectors $k$ for which $a_i^{(k)} = 0$.

We now discuss the correspondence of Durfee systems with multipartitions. Suppose we have a Durfee system $(Q^{(k)}, a^{(k)}, b^{(k)})$ for $K \in GL(n, \mathbb{Z}_+)$ Consider (2.6) for $p = 0$. The left-hand side is the generating series for all multipartitions $(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(n)})$. Each term in the summand on the right-hand side of (2.6) is a product (over $i$) of terms of the form

\[
(2.7) \quad \frac{q^{(m+a)(n+b)}}{(q)_m(q)_n}.
\]

By associating to (2.7) a set of partitions of the form indicated in Figure 2.1, each term in the summand on the right-hand side of (2.6) is in 1–1 correspondence with a set of multipartitions.

One possible strategy for proving the existence of a Durfee system is therefore to show that the set of $n$-dimensional multipartitions corresponding to the right-hand side of (2.6) is non-overlapping and exhaustive. By keeping track of the number of rows and columns in each partition $\lambda^{(i)}$, the generalization (2.1) then easily follows.

After discussing some examples of Durfee systems in the following sections we will explore some further consequences in the context of affine Lie algebra characters.

### 3. Examples

In this section we will consider some examples of Durfee systems.
FIGURE 3.1. The $k = 0$ sector

\[ \begin{pmatrix} \cdot & \cdot \\ \cdot & \cdot \end{pmatrix} \]

$\mathbf{m} = (0,0)$

\[ \begin{pmatrix} \cdot & \cdot \\ \cdot & \cdot \end{pmatrix} \]

$\mathbf{(1,0)}$

\[ \begin{pmatrix} \cdot & \cdot \\ \cdot & \cdot \end{pmatrix} \]

$\mathbf{(0,1)}$

\[ \begin{pmatrix} \cdot & \cdot \\ \cdot & \cdot \end{pmatrix} \]

$\mathbf{(1,1)}$

\[ \begin{pmatrix} \cdot & \cdot \\ \cdot & \cdot \end{pmatrix} \]

$\mathbf{(2,0)}$

\[ \cdots \]

FIGURE 3.2. Some missing bipartitions

\[ \begin{pmatrix} \cdot & \cdot \\ \cdot & \cdot \end{pmatrix} \]

THEOREM 3.1. Consider the matrix $K \in GL(2, \mathbb{Z}_+)$ given by

\[(3.1) \quad K = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}.\]

We have a Durfee system $(Q^{(k)}, a^{(k)}, b^{(k)})$ for $K$ given by

\[
Q^{(0)} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \quad a^{(0)} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \quad b^{(0)} = \begin{pmatrix} 0 \\ 0 \end{pmatrix},
\]

\[
Q^{(1)} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad a^{(1)} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad b^{(1)} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}.
\]

Let us illustrate, in some detail, how one might arrive at this result. The $k = 0$ term in (2.6) (for $p = 0$) is explicitly given by

\[(3.2) \quad \sum_{\begin{subarray}{c} n_1 - (m_1 + m_2) = 0 \\ n_2 - (m_1 + 2m_2) = 0 \end{subarray}} q^{n_1 m_1 + n_2 m_2} \frac{(q)_{n_1} (q)_{n_2} (q)_{m_1} (q)_{m_2}}{(q)_{n_1} (q)_{n_2}}.
\]

The set of bipartitions $(\lambda^{(1)}, \lambda^{(2)})$ associated to (3.2), according to the prescription of Section 2, is depicted in Figure 3.1 for low values of $\mathbf{m} = (m_1, m_2)$. 
Figure 3.3. The $k = 1$ sector

Figure 3.4. The $k = 0$ sector

Figure 3.5. The $k = 1$ sector
Clearly these do not exhaust the set of all bipartitions. For instance, if \( \lambda^{(1)} = \emptyset \) (indicated by a \( \bullet \) in Figure 3.1) and \( \lambda^{(2)} \neq \emptyset \), then \( \lambda^{(2)} \) necessarily has two or more rows. Thus, the set of bipartitions depicted in Figure 3.2 is missing in (3.2).

If this set of bipartitions is to be included as the \( m = (0, 0) \) term of another sector, say \( k = 1 \), then this immediately fixes all components of \( (Q^{(1)}, a^{(1)}, b^{(1)}) \) with the exception of \( b_1^{(1)} \). (Note that this component is also unconstrained by consideration of the two \( 1 \times 1 \) sub-blocks of \( K \), as discussed in Section 2.) Consideration of the \( m = (1, 0) \) term in the \( k = 1 \) sector, however, uniquely fixes \( b_1^{(1)} \) as well and we arrive at the conclusion that (3.2) needs to be supplemented by

\[
\sum_{n_1 = (m_1 + m_2) + 1} q^{(n_1 + 1) m_1 + n_2 (m_2 + 1)} (q)_{n_1} (q)_{n_2} (q)_{m_1} (q)_{m_2}.
\]

The set of bipartitions in the \( k = 1 \) sector, arising from (3.3) for low values of \( m \), is depicted in Figure 3.3.

Together, the sets of bipartitions of Figures 3.1 and 3.3 are seen to be non-overlapping and to exhaust the set of all bipartitions, at least to low order, so it seems that no other sectors are required. The proof that this works to all orders requires a bit more work and will be omitted.

A slightly more complicated Durfee system is given in

**Theorem 3.2.** Let

\[
K = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}.
\]

The following constitutes a Durfee system for \( K \)

\[
\begin{aligned}
Q^{(0)} &= \begin{pmatrix} 0 \\ 0 \end{pmatrix}, & a^{(0)} &= \begin{pmatrix} 0 \\ 0 \end{pmatrix}, & b^{(0)} &= \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \\
Q^{(1)} &= \begin{pmatrix} 0 \\ 1 \end{pmatrix}, & a^{(1)} &= \begin{pmatrix} 0 \\ 1 \end{pmatrix}, & b^{(1)} &= \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \\
Q^{(2)} &= \begin{pmatrix} 1 \\ 1 \end{pmatrix}, & a^{(2)} &= \begin{pmatrix} 1 \\ 0 \end{pmatrix}, & b^{(2)} &= \begin{pmatrix} 0 \\ 0 \end{pmatrix}.
\end{aligned}
\]
The reasoning parallels that of Theorem 3.1. The first few sets of contributing bipartitions, for the sectors \( k = 0, 1, 2 \), are depicted in Figures 3.4–3.6, respectively.

Theorem 3.2 has the following higher dimensional generalization

**Theorem 3.3.** Let \( K \in GL(n, \mathbb{Z}_+) \) be defined by

\[
K = \begin{pmatrix}
2 & 1 & \cdots & 1 \\
1 & 2 & \cdots & 1 \\
\vdots & \vdots & \ddots & \vdots \\
1 & 1 & \cdots & 2
\end{pmatrix}.
\]

(3.6)

We have a Durfee system of length \( L = n + 1 \), given by the \( n \)-vectors

\[
Q^{(k)} = \left(0, 0, \ldots, 0, 1, \ldots, 1\right),
\]

(3.7)

\[
a^{(k)} = \left(0, \ldots, 0, 1, 0, \ldots, 0\right),
b^{(k)} = \left(0, 0, \ldots, 0\right),
\]

for \( k = 0, \ldots, n \).

**Remark.** Note that the length of the Durfee system in Theorem 3.3 is given by

\[ L = n + 1 = \det K. \]

We believe this is a general feature of Durfee systems for which \( b^{(k)} = 0 \) for all \( k = 0, \ldots, L - 1 \) (see also the discussion in Section 6). 

**4. Shift operation**

It turns out that, once a Durfee system for some \( K \in GL(n, \mathbb{Z}_+) \) has been established, it is rather straightforward to obtain a Durfee system for a class of deformations of \( K \). These deformations are given in terms of a ‘charge vector’ \( t = (t_1, \ldots, t_n) \), \( t_i \in \mathbb{Z}_+ \), and a positive integer \( M \in \mathbb{Z}_+ \) as (These deformations were motivated by the ‘shift operation’ on \( K \)-matrices describing fractional quantum Hall systems (see [5] and references therein).)

\[
K_{M,t} = K + Mt t^T.
\]

(4.1)

For instance, consider the deformation \( K_{M,t} \) of the two-dimensional identity matrix

\[
K_{M,t} = \begin{pmatrix}
t_1^2 M + 1 & t_1 t_2 M \\
t_1 t_2 M & t_2^2 M + 1
\end{pmatrix},
\]

(4.2)

where we can assume that \( t_1 \leq t_2 \). Note that the matrix \( K \) of (3.4) is of this form with \( M = 1, t = (1, 1) \).
**Theorem 4.1.** The matrix \( K_{M,t} \) of (4.2) admits a length \( L = (t_1^2 + t_2^2)M + 1 \) Durfee system. There are \( t_2^2 M \) sectors given by

\[
Q = \begin{pmatrix}
(t_1^2 M + 1) & (t_1^2 M + 1) & \cdots & (t_1^2 M + 1) \\
(t_1^2 M) & (t_1^2 M - 1) & \cdots & (0)
\end{pmatrix}
\]

with \( a = \binom{0}{0} \), \( b = \binom{0}{0} \). \( t_2^2 M \) sectors given by

\[
Q = \begin{pmatrix}
(t_1^2 M) & (t_1^2 M - 1) & \cdots & (1)
\end{pmatrix}
\]

with \( a = \binom{1}{0} \), \( b = \binom{0}{0} \), and the ‘vacuum sector’ \( Q = \binom{0}{0} \), \( a = \binom{0}{0} \), \( b = \binom{0}{0} \).

For deformations (4.1), with \( K = 1 \), we have

\[
\det K_{M,t} = (t^T \cdot t)M + 1
\]

which can be written as

\[
\det K_{M,t} = \text{Tr}(K_{M,t} - \mathbb{1}) + 1.
\]

In fact, if \( n = 2 \), the matrix \( K_{M,t} = 1 + M t t^T \) is the most general symmetric, non-negative integer-valued matrix satisfying (4.6). Note that the length of the Durfee system in Theorem 4.1 is again given by \( \det K_{M,t} \).

5. The UCPF and character identities

Consider the ‘Universal Chiral Partition Function’ (UCPF) (see [6] and references therein)

\[
Z(K; Q, u|z; q) = \sum_{m \in \mathbb{Z}_+} \left( \prod_{i} y_i^{m_i} \right) q^{2m} K = Q \prod_{i} \left[ (1 - K) \cdot m + u \right],
\]

where \( K \in GL(n, \mathbb{Z}_+) \), \( Q_i \in \mathbb{Z}_+ \) and \( u_i \in \mathbb{Z}_+ \cup \{\infty\} \), \( i = 1, \ldots, n \). (The considerations in this section can easily be generalized to triples \( (K, Q, u) \) with entries in \( \mathbb{Q} \), provided appropriate restrictions on the summation variables \( m_i \) in (5.1) are made.)

The following theorem is derived by elementary algebra
THEOREM 5.1. Assume that \((Q^{(k)}, a^{(k)}, b^{(k)})\) forms a Durfee system for a symmetric \(K \in GL(n, \mathbb{Z})\). Define
\[
Q^{(k)} = -K^{-1} \cdot Q^{(k)}, \quad z'_i = \prod_j z_j^{-K_{ij}}.
\]
Then we have the following identity
\[
\sum_k \left(\prod_i z_i^{-Q_i^{(k)}}\right) q^{k\cdot K_{i} - 1} q^{a^{(k)}+b^{(k)}} Z(K; Q^{(k)} + b^{(k)}, M - (Q^{(k)} + b^{(k)})|z'; q)
\]
\[
\times Z(K^{-1}; Q^{(k)} + a^{(k)}, N - (Q^{(k)} + a^{(k)})|z; q)
\]
\[
= \sum_{p \in \mathbb{R}} \left(\prod_i z_i^{p}\right) q^{z_p K^{-1} - 1} \prod_i \left[ M_i + N_i + ((1 - K^{-1}) \cdot p)_i \right].
\]
for all \(M, N \in \mathbb{Z}^n\).

REMARK. Note that the polynomials \(P_M(z; q) \equiv Z(K; Q^{(k)} + b^{(k)}, M - (Q^{(k)} + b^{(k)})|z; q)\) and \(Q_N(z; q) \equiv Z(K^{-1}; Q^{(k)} + a^{(k)}, N - (Q^{(k)} + a^{(k)})|z; q)\), entering (5.3), all arise as a solution to the same (that is, \(k\)-independent) set of recursion relations \((i = 1, \ldots, n)\) [5]
\[
P_M(z; q) = P_{M-e_i}(z; q) + z'_i q^{4K_{e_i} + M} P_{M-K \cdot e_i}(z; q),
\]
\[
Q_N(z; q) = Q_{N-e_i}(z; q) + z'_i q^{4K_{-e_i} + N} Q_{N-K \cdot e_i}(z; q),
\]
where \(e_i\) denotes the unit vector in the \(i\)-direction and where we have used
\[
\begin{bmatrix} M \\ m \end{bmatrix} = \begin{bmatrix} M - 1 \\ m \end{bmatrix} + q^{M-m} \begin{bmatrix} M - 1 \\ m - 1 \end{bmatrix}.
\]

For the application of Theorem 5.1 to affine Lie algebra characters let us consider the limiting form of (5.1) as \(u \to \infty\), that is,
\[
Z_\infty(K; Q|z, q) = \lim_{u \to \infty} Z(K; Q, u|z, q) = \sum_m \left(\prod_i z_i^{m}\right) q^{z_m K - m q^m} \prod_i (q_m)^{m}.
\]

REMARK. The limiting UCPF’s are not all independent. For instance, by using the simple relation \((1 - q^m)/(q)_m = 1/(q_{m-1})\) we find
\[
Z_\infty(K; Q) = Z_\infty(K; Q + e_i) + z'_i q^{4K_{e_i} + Q \cdot e_i} Z_\infty(K; Q + K \cdot e_i).
\]

By taking \(M \to \infty\) in (5.3) we obtain
**Corollary 5.2.** Let \((Q^{(k)}, a^{(k)}, b^{(k)})\) be a Durfee system for \(K \in GL(n, \mathbb{Z}_e)\) of length \(L\). Define \(Q^{(k)}\) and \(z'_i\) by (5.2). We then have

\[
(5.7) \quad \sum_{k=0}^{L-1} \left( \prod_{i} z'_i \right)^{-Q^{(k)} + a^{(k)} + b^{(k)}} Z_{\infty}(K; Q^{(k)} + b^{(k)}|z'; q) 
\times Z_{\infty}(K^{-1}; Q^{(k)} + a^{(k)}|z'; q) = \frac{1}{(q)_{\infty}^{n}} \sum_{p \in \mathbb{Z}^n} \left( \prod_{i} z'_i \right)^{p_{\cdot} K^{-1} \cdot p}.
\]

Now suppose that the bilinear form \(p \cdot K^{-1} \cdot p\) is chosen in such a way that it equals the standard bilinear form on the weight lattice \(\Lambda_w\) of a simple Lie algebra \(g\) of rank \(n\) and that the sum over \(p \in \mathbb{Z}^n\) corresponds to the sum over the weight lattice. Then, provided \(g\) is simply-laced, the right-hand side of (5.7) can be recognized as the Frenkel-Kac character of the sum of the level-1 integrable highest weight modules of the affine Lie algebra \(\widehat{g}\) (see, for example, [9]). (The irreducible characters can be recovered by suitably restricting the sum over \(p\).) Thus, in such cases, Corollary 5.2 provides an expression for the level-1 characters of \(\widehat{g}\) in terms of UCPF’s based on the bilinear form constructed out of \(K \oplus K^{-1}\). This has important applications in the study of quasiparticles in the conformal field theory descriptions of certain non-Abelian fractional quantum Hall states [4, 5]. In fact, these applications were the main motivation for the present study.

As an example, consider \(g = \mathfrak{sl}_{n+1}\). The weights \(\{\epsilon_1, \ldots, \epsilon_{n+1}\}\), of the fundamental \((n+1)\)-dimensional representation \(L(\Lambda_1)\) of \(\mathfrak{sl}_{n+1}\) satisfy \(\epsilon_i \cdot \epsilon_j = \delta_{ij} - 1/(n+1)\). A suitable basis of the weight lattice \(\Lambda_w\) is given by the \(\epsilon_i, i = 1, \ldots, n\) (see Figure 5.1 for \(\mathfrak{sl}_2\)). Now note that \((\sum_i p_i \epsilon_i) \cdot (\sum_j p_j \epsilon_j) = p \cdot K^{-1} \cdot p\), where \(K^{-1}\) is given by

\[
(5.8) \quad K^{-1} = \frac{1}{n+1} \begin{pmatrix}
 n & -1 & \cdots & -1 \\
 -1 & n & \cdots & -1 \\
 \vdots & \vdots & \ddots & \vdots \\
 -1 & -1 & \cdots & n
\end{pmatrix},
\]

which has an inverse \(K\) given by (3.6). The ‘dual sector’, defined by \(K\), corresponds to a particular basis of the root lattice of \(\mathfrak{sl}_{n+1}\) (see Figure 5.1 for \(\mathfrak{sl}_3\)). The weights of this basis are determined by (5.2).

Thus, the sum over \(p \in \mathbb{Z}^n\) is precisely over the weight lattice of \(\mathfrak{sl}_{n+1}\) and combining Theorem 3.3 and Corollary 5.2 gives us an expression for the character of the (sum over all) level-1 integrable highest weight modules of \(\mathfrak{sl}_{n+1}\). As a consistency check, note that

\[
\frac{1}{2} Q^{(k)} \cdot K^{-1} \cdot Q^{(k)} = \frac{k(n+1-k)}{2(n+1)}, \quad k = 0, \ldots, n,
\]
is indeed precisely the conformal dimension of the level-1 integrable highest weight module $L(\Lambda_k)$ of $\mathfrak{sl}_{n+1}$.

6. Discussion and conclusions

In this paper we have presented higher dimensional analogues of the classical Durfee square formula (1.1) in the form of ‘Durfee systems’, we explained their correspondence to multipartitions, and gave a few examples. We have also remarked on the application of Durfee systems, in particular with regards to writing (chiral) characters of two-dimensional conformal field theories in UCPF form.

A number of obvious questions come to mind. Firstly, for which symmetric $K \in GL(n, \mathbb{Z}_+)$ is it possible to find a Durfee system? It seems that this class of matrices is quite big. In fact, examples suggest that, provided $\det K \geq 0$, a Durfee system always exists (see (2.3) for an example with $\det K = 0$). Secondly, how unique are Durfee systems for a given matrix $K$? Clearly they are not unique. For instance, in the case of $K = s/r$ (see Theorem 2.2) we can construct Durfee systems of length $L = m''rs$ for all $m \in \mathbb{N}$ by taking $(r,s) \rightarrow (mr,ms)$ in (1.6) and (1.7). Similar constructions exist for the higher dimensional cases. Another source of non-uniqueness originates from possible symmetries of the matrix $K$. For example, interchanging the components of all vectors $(Q^{(k)}, a^{(k)}, b^{(k)})$ in Theorem 3.2, provides another Durfee system due to the $\mathbb{Z}_2$ permutation symmetry of the matrix $K$ in (3.4). Thirdly, for a given $K$, what is the minimal length $L_{\text{min}}$ of a Durfee system? It seems that a special role is played by matrices for which $L_{\text{min}} = \det K$, which seem to be closely related to matrices for which it is possible to choose a Durfee system for which $b^{(k)} = 0$ for all $k$. A large class of such matrices is provided by the shift deformations $K_{M,t}$ of the identity (see (4.1)) and, at least in two dimensions, it appears that such deformations exhaust all matrices $K$ for which $L_{\text{min}} = \det K$. Finally, is it possible to give a more ‘geometric’ construction of the vectors $(Q^{(k)}, a^{(k)}, b^{(k)})$? Again, in the case of matrices $K$ for which $L_{\text{min}} = \det K$ it seems that the set of $Q^{(k)}$ is given by a set of coset representatives (with minimal non-negative components) of $\mathbb{Z}^n$ modulo...
the equivalences $m \sim m + K \cdot e_i (i = 1, \ldots, n)$. Note that in the case of (3.6) the
equivalence preserves the $\mathbb{Z}_{n+1}$ charge $q = \sum im_i \pmod{n + 1}$ of $m$ (‘$n$-ality’) and
that we find one coset representative for each $q \in \mathbb{Z}_{n+1}$.
